

# *Making sense of sensors: The prediction of hypocalcemia*

**Meike van Leerdam**, Arno Liseune, Peter R. Hut, Elena Slavco,  
Jan Hulsen, and Miel Hostens

## The Transition Period

The most challenging time...

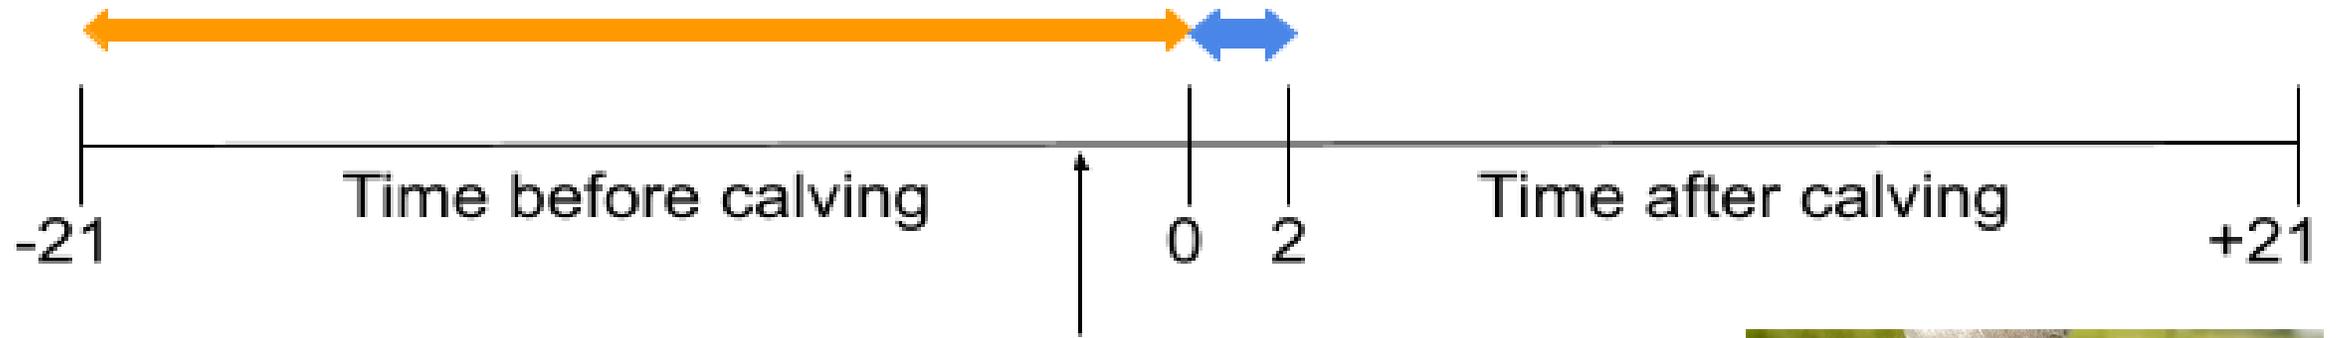

## Hypocalcemia

- Sudden increase in calcium demand
- Clinical vs Subclinical
- Associated with many other diseases

## Why predict hypocalcemia

- Difficult to evaluate
- High prevalence (up to 69%)
- Tool to identify animals at risk of transition disease
- Monitoring of the calcium status of the herd
  - Evaluate preventive measures or diet changes
  - Direct focus of herd analysis

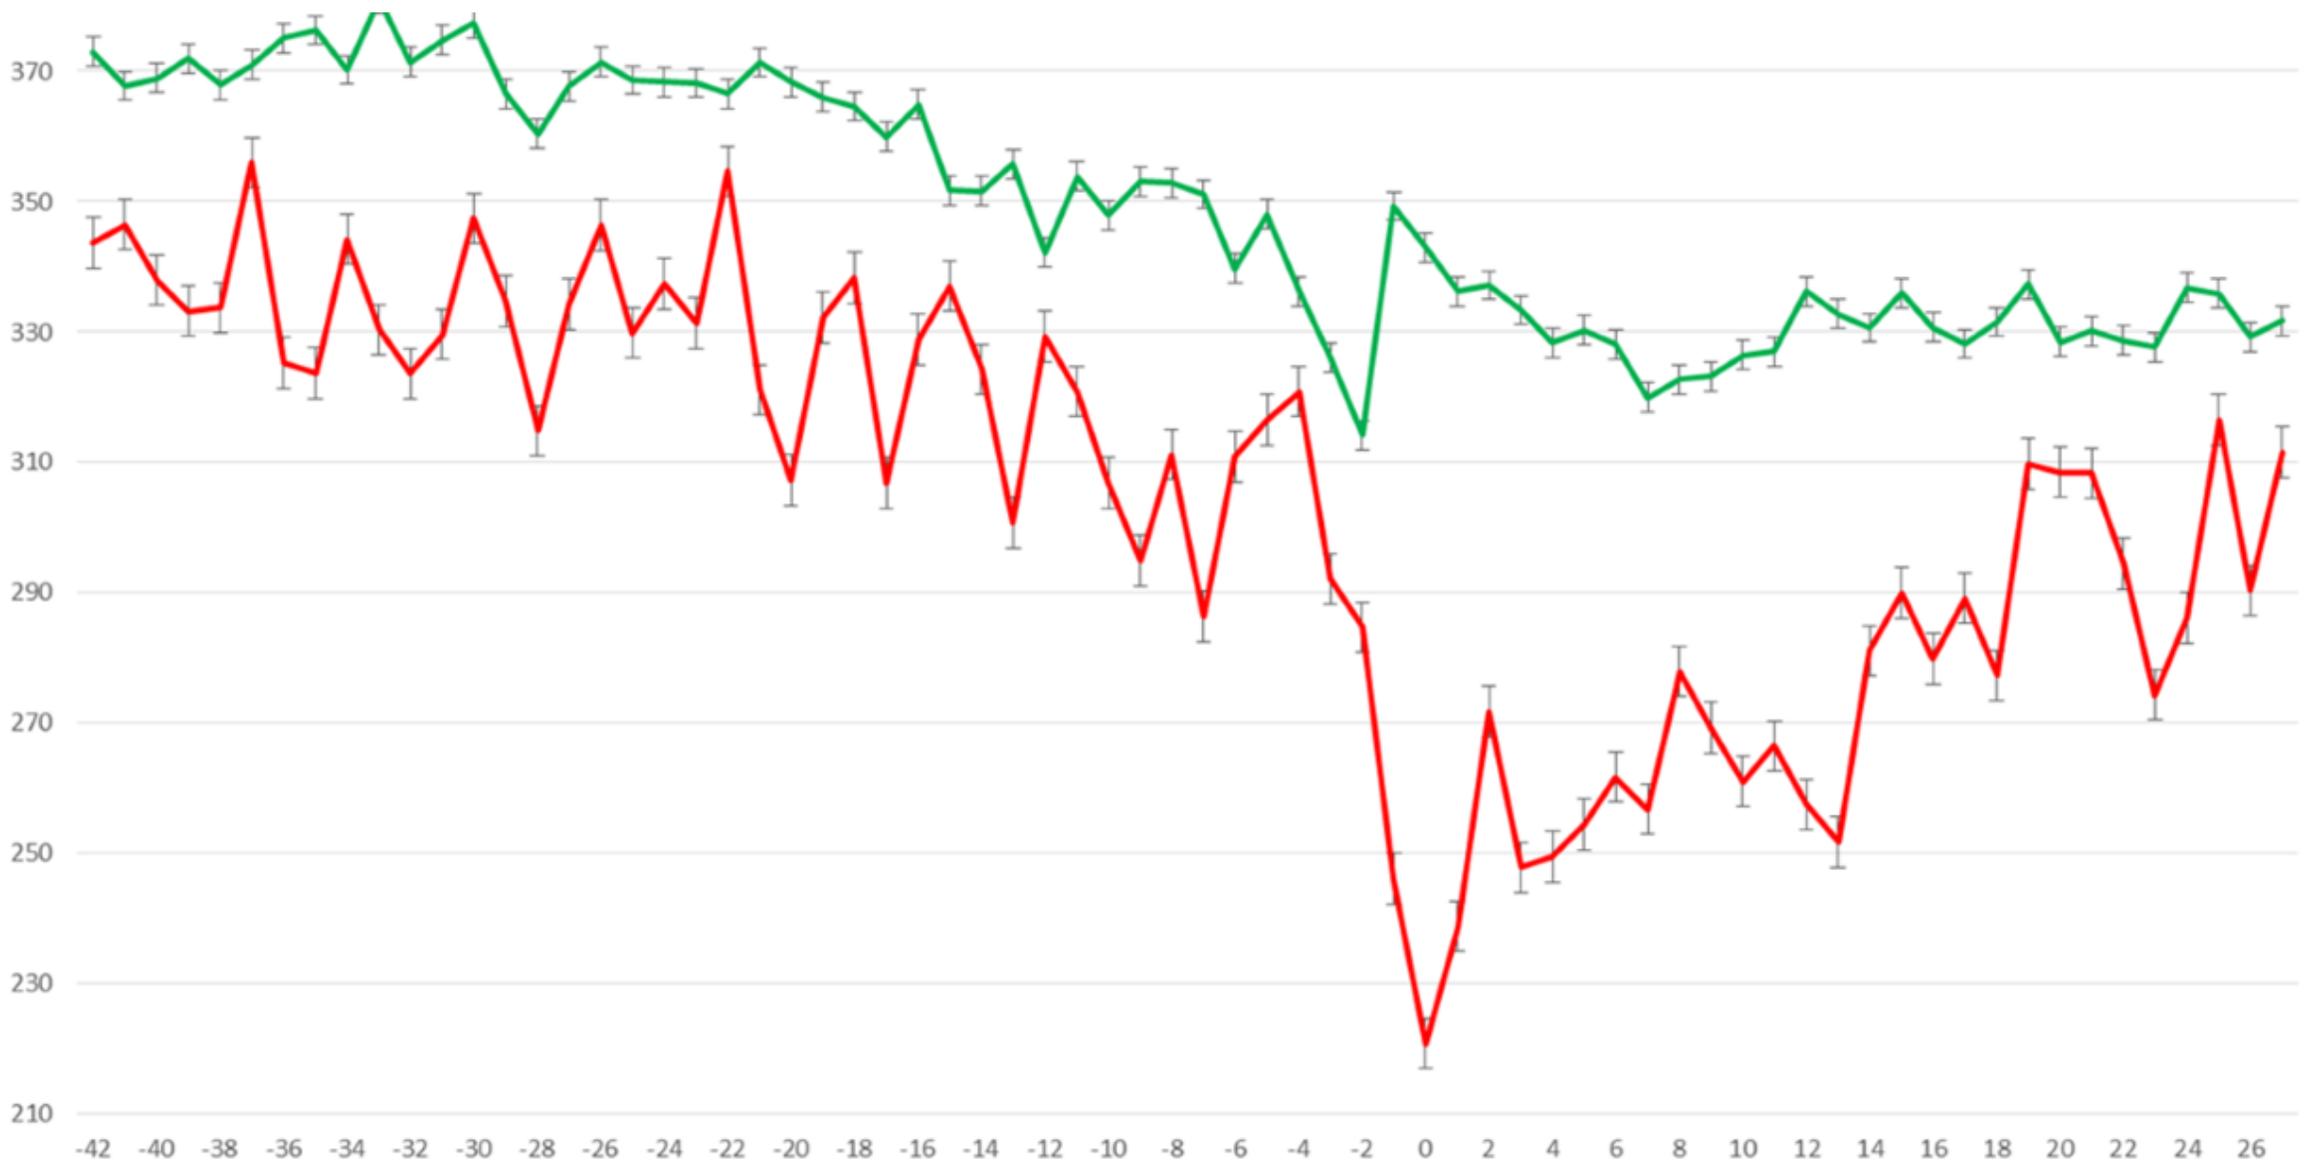

Locomotionscore  
BCS

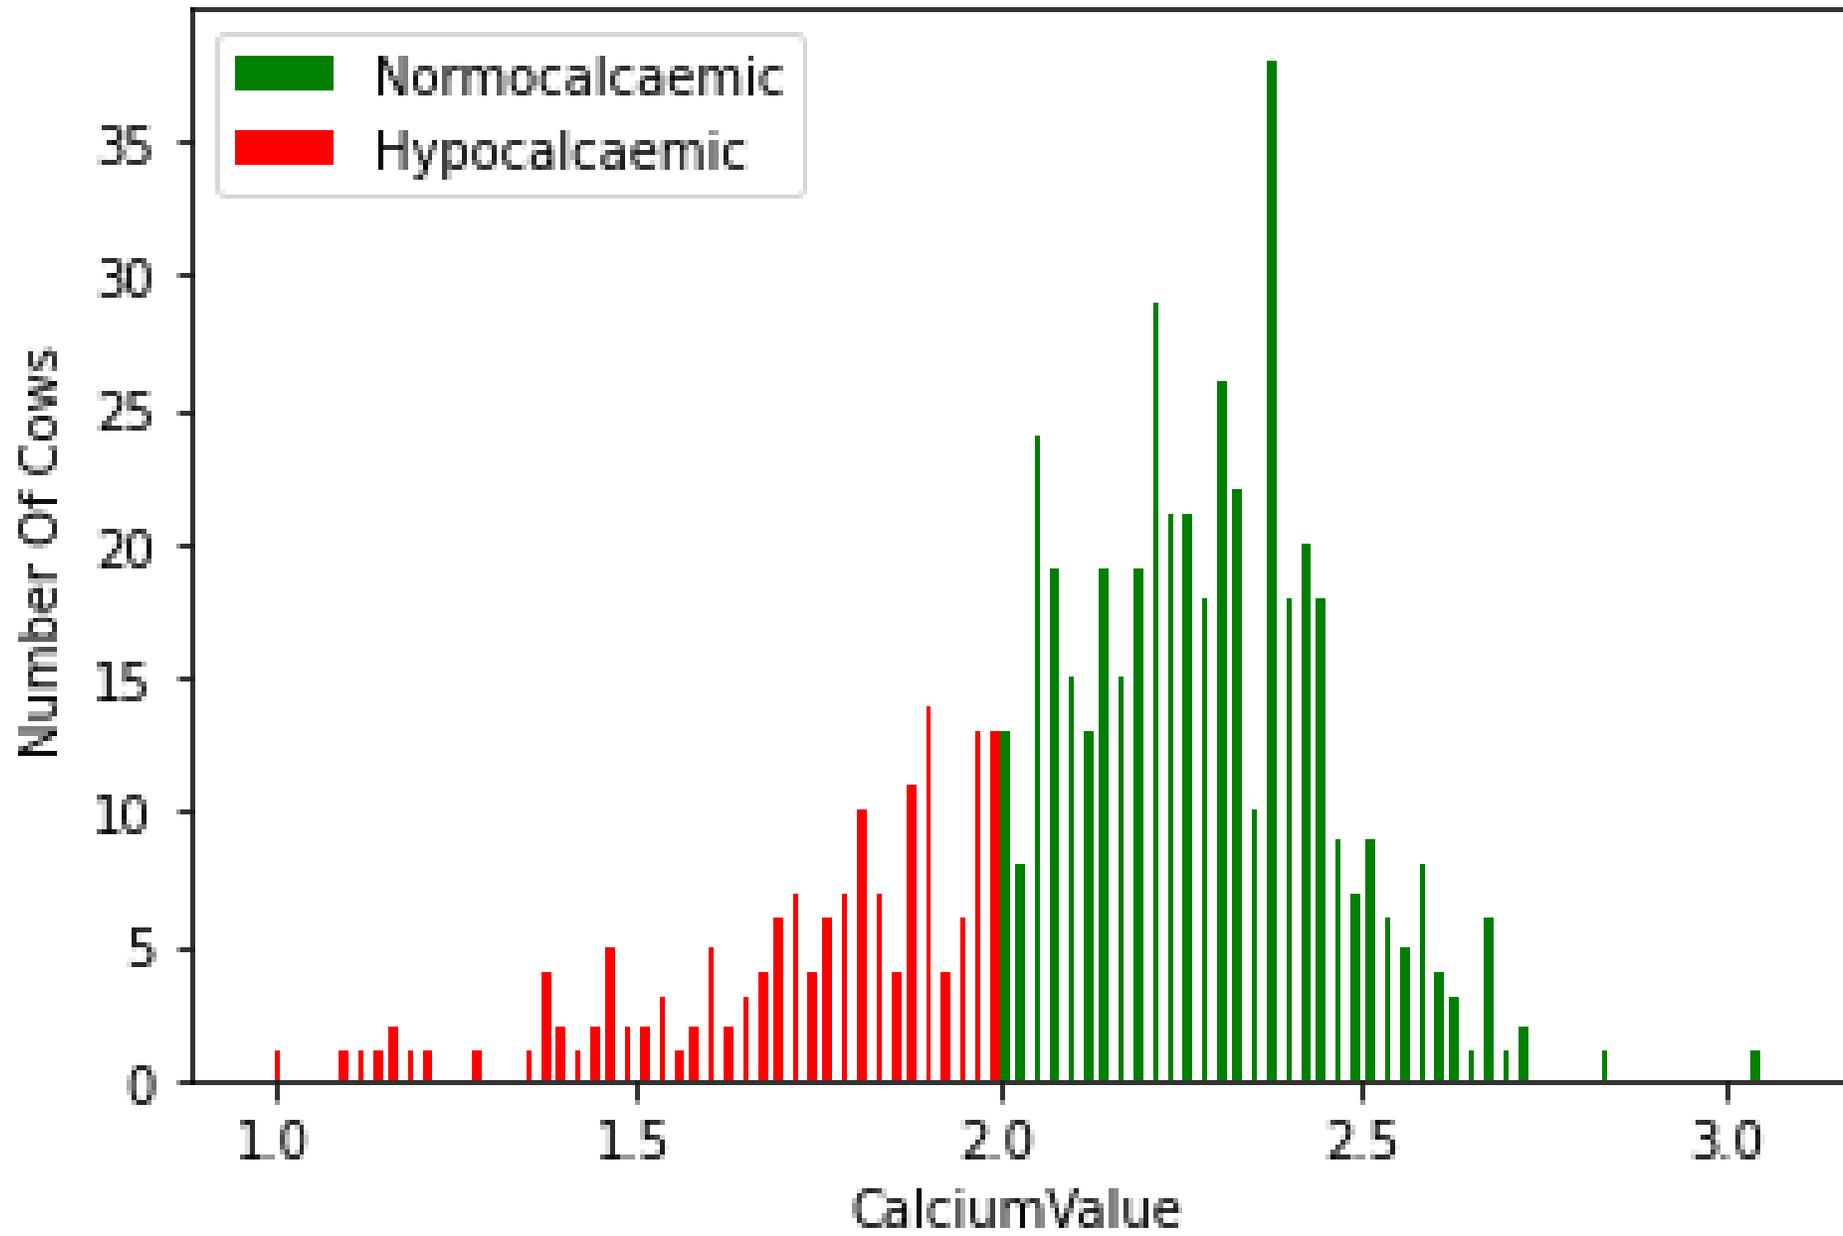

The Transition Period

Eating time  
minutes/day

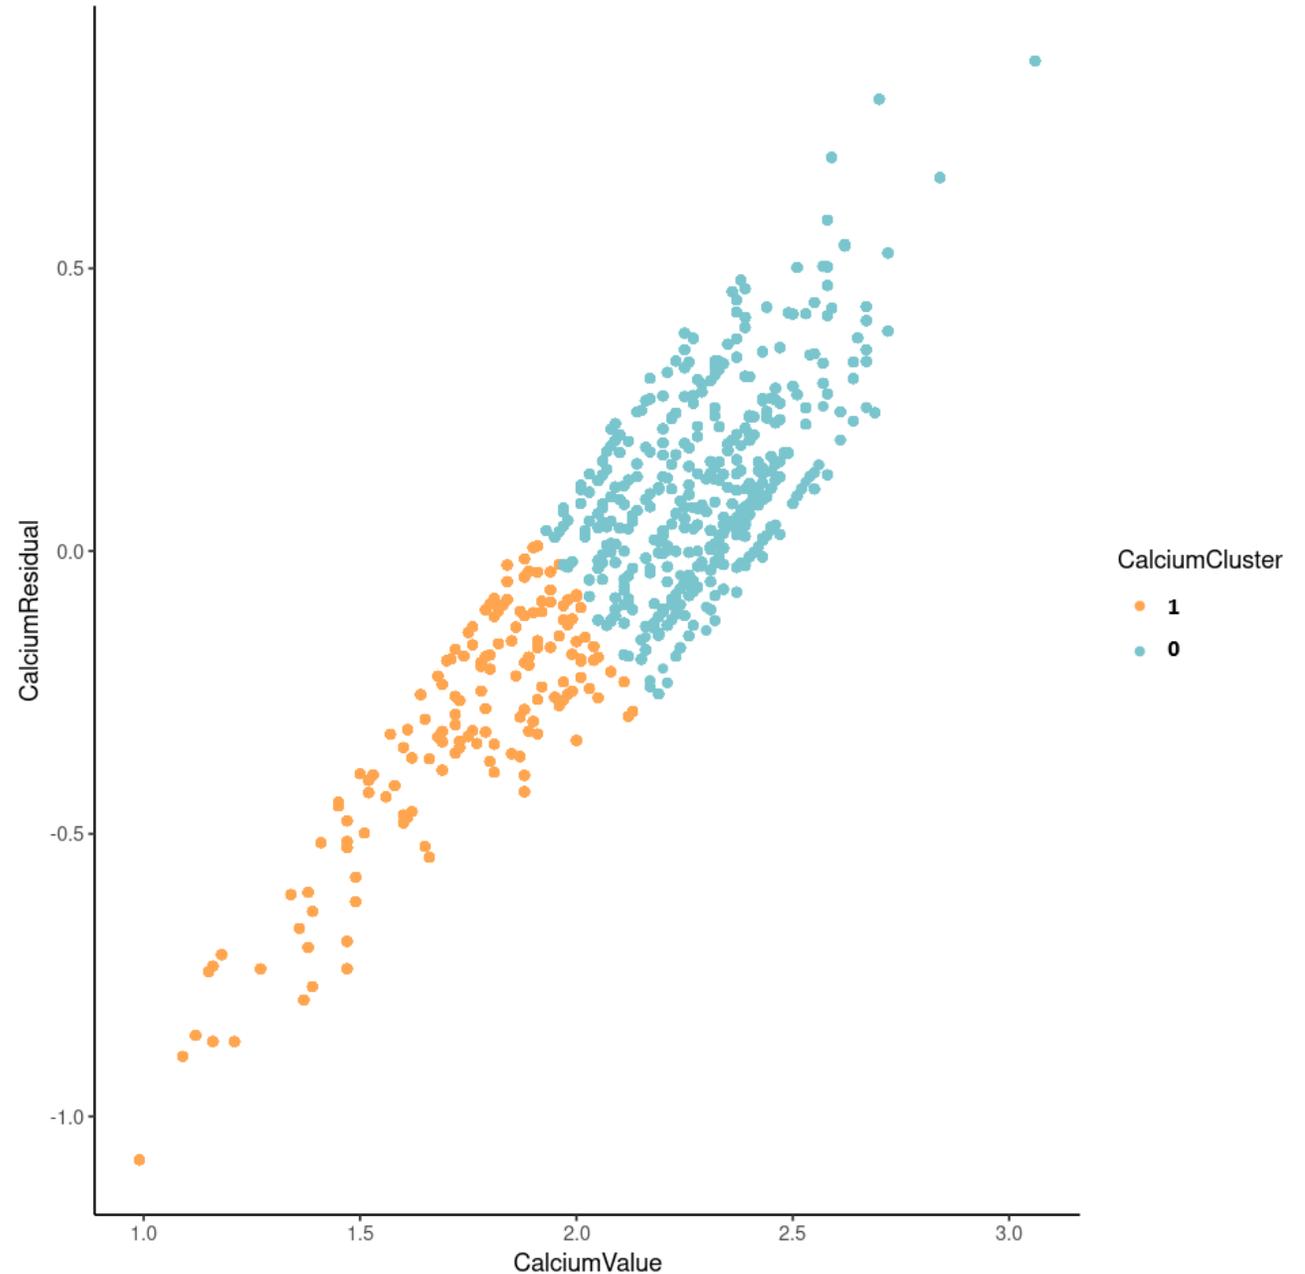

— Gemiddelde >1.80 — Gemiddelde <1.80

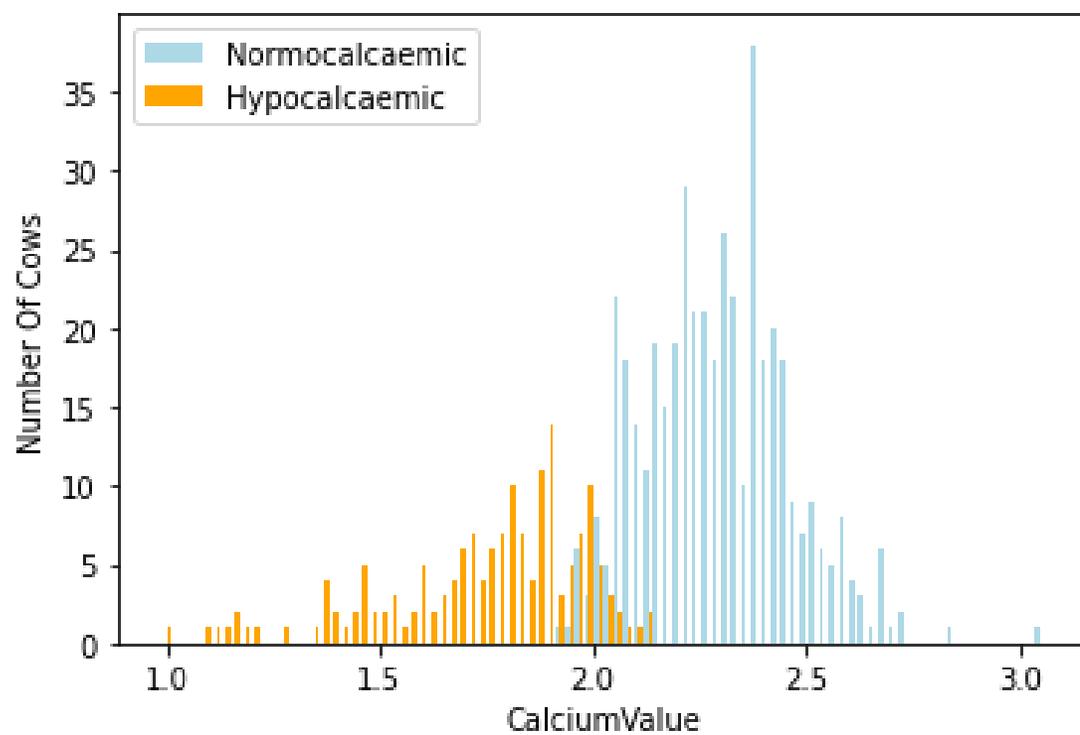

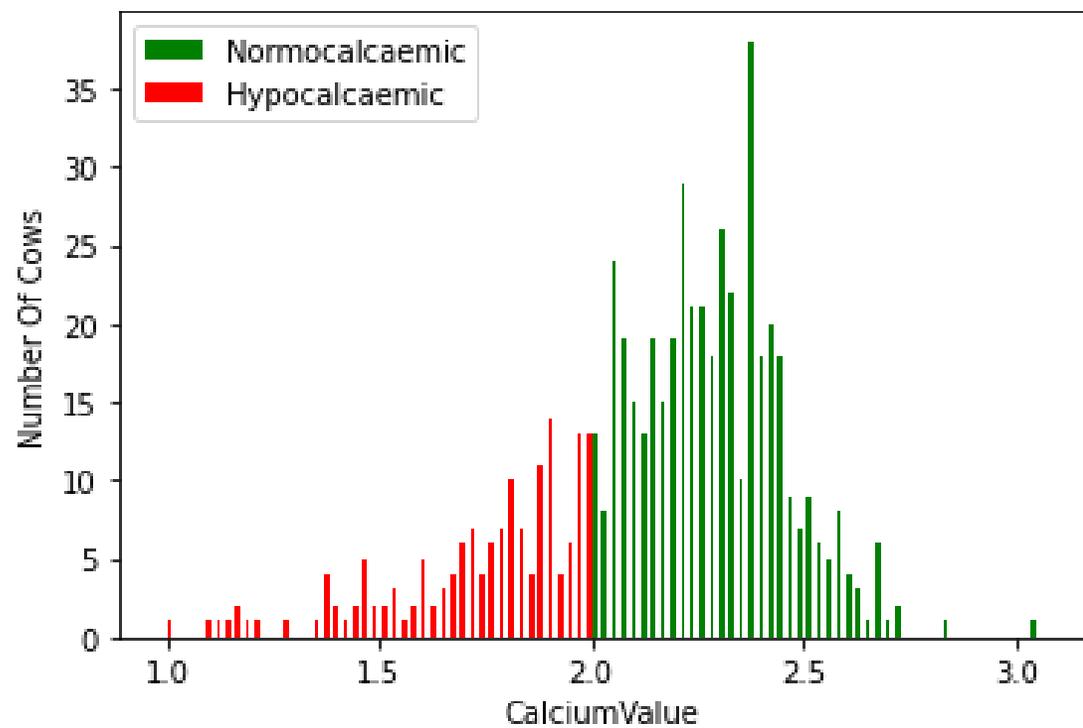

# Clusters as an alternative way of dividing the data

Linear mixed-effects model combined with k-means clustering

Compensates for: Parity, farm and day of calcium measurements

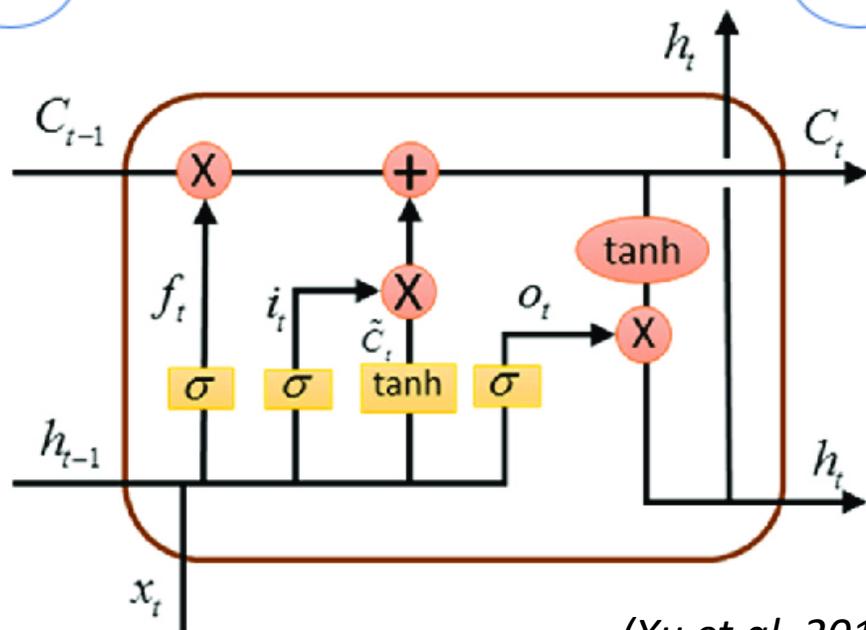

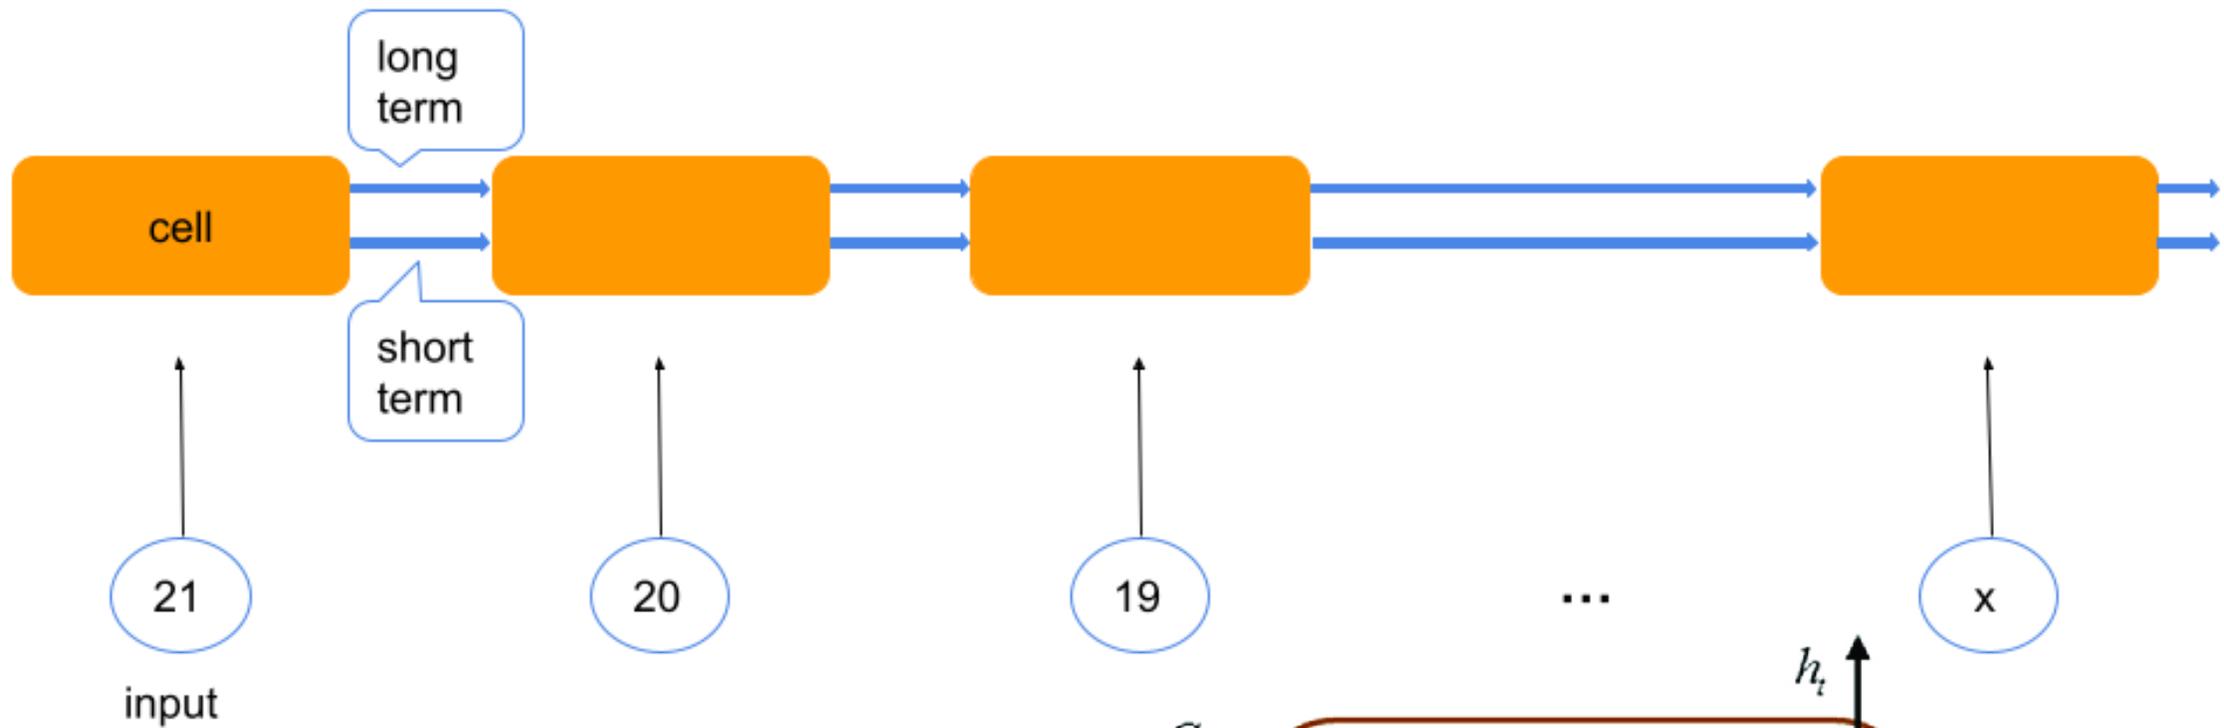

*The models*

## **3 Different kinds of models**

- Logistic regression
- XgBoost
- LSTM deep learning model

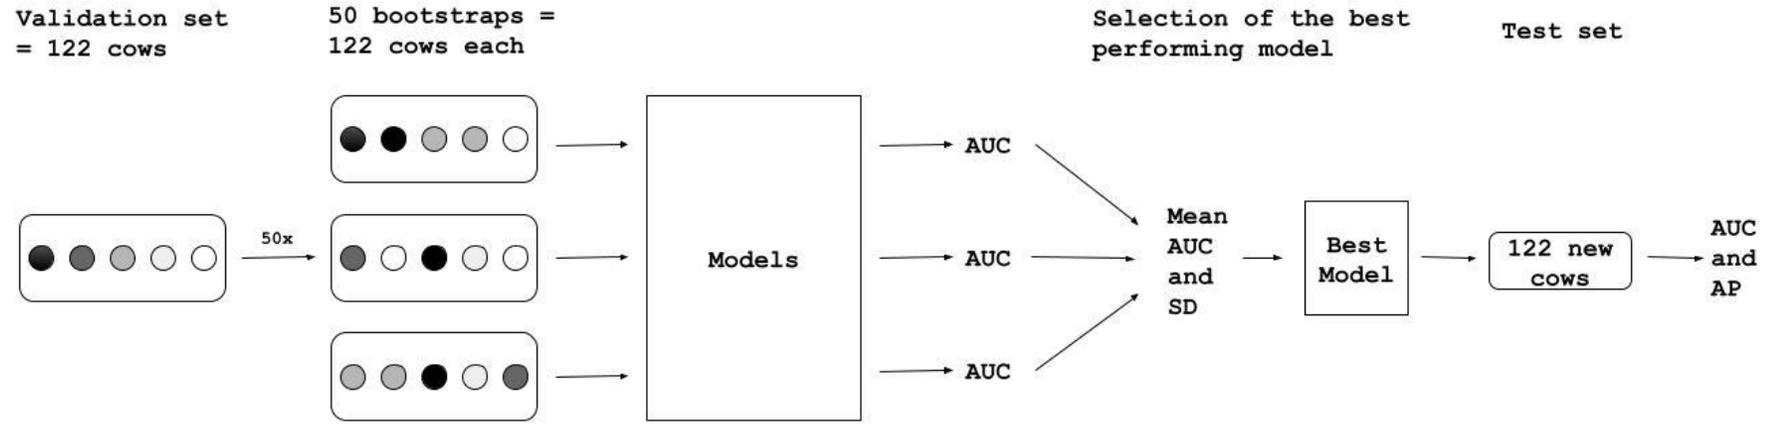

An LSTM

(Xu et al. 2017)

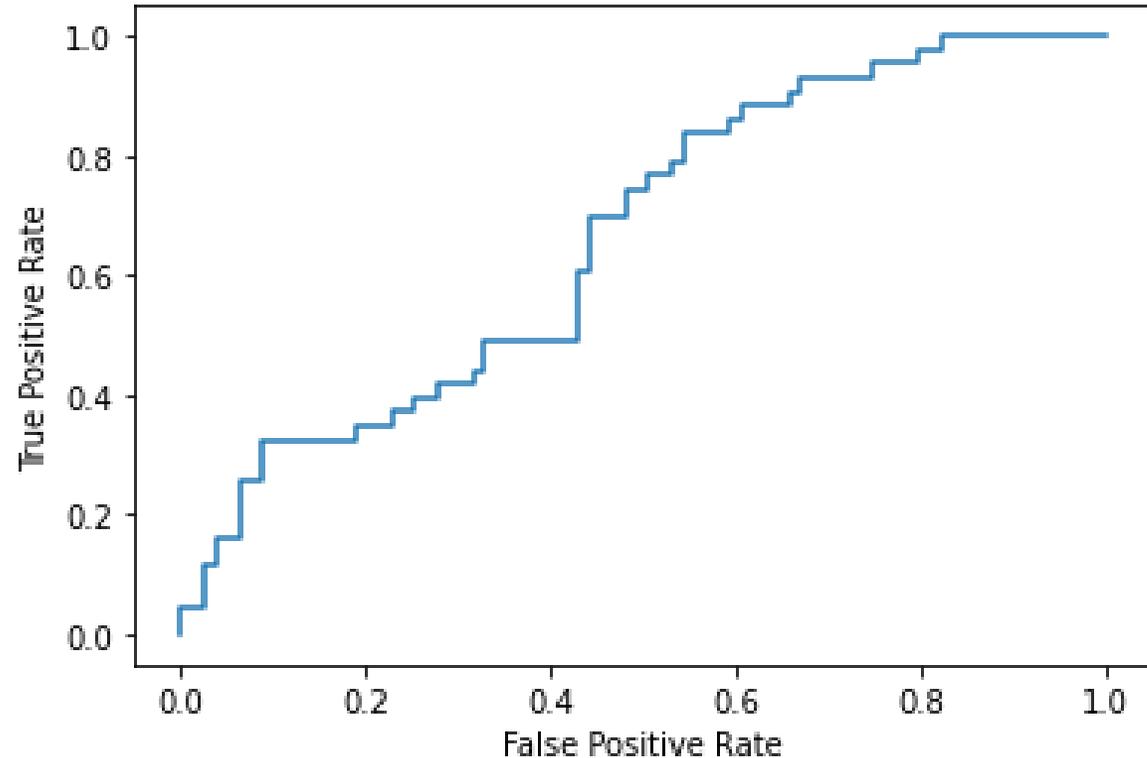

## Hyperparameter tuning

- Find the best configuration
- Take random samples
- Add parity, day of measurement and calving season
- Add BCS and locomotion score

# Model evaluation

- 50 Bootstraps > random samples of the validation set
- AUC > Area under the ROC-curve
- Standard Deviation

Clusters or cut-off y-values	Upsampling	Static features set	AUC	SD
Cluster	+	-	0,49	0.071
Cluster	-	-	0.59	0.061
Cut-off	+	-	0,61	0.062
Cluster	+	Small	0,61	0.058
Cut-off	-	-	0.64	0.074
Cluster	-	Small	0.66	0.054
Cluster	+	All	0.66	0.043
Cut-off	+	All	0.67	0.069
Cluster	-	All	0.68	0.060
Cut-off	+	Small	0.70	0.063
Cut-off	-	All	0.71	0.067
Cut-off	-	Small	0.71	0.057

## Results

The best performing model:

- Predicts groups based on the cut-off value
- Does not use upsampling
- Uses sensor data
- Also uses calving season, parity and day of measurements
- Does not use BCS and Locomotion score

## Results of the final models

The never used test set, used on the best models

Logistic Regression	AUC 0,57 and AP 0,45
XgBoost	AUC 0,58 and AP 0,43
LSTM model	AUC 0,66 and AP 0,53

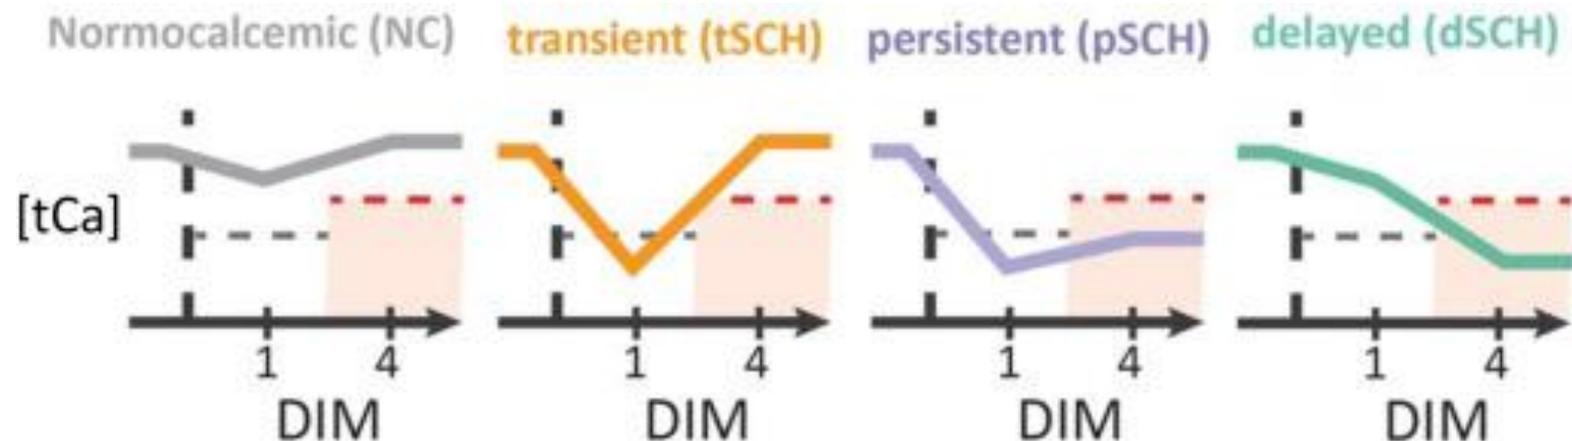

*But...*

## **Improving model performance**

- Improve input and output quality
- Use non disruptive missing value imputation
- Increase the amount of training data
- Add more features with association to hypocalcemia
- Drop features with less additional predictive value

## Zooming in on hypocalcemia

- Clinical hypocalcemia > impairs animal welfare, farm economics, fertility and transition success
- Subclinical hypocalcemia > effect onset dependent
  - Transient
  - Delayed
  - Persistent
- Effect of inflammatory response and reduced feed intake?

(McArt et al. 2023)

## Old-fashioned cut-off?

- 2,0 mmol/L seems arbitrarily chosen in the past
- Possible alternative: clusters > context-based cut-off
- Future research:
  - Association with the outcome of interest
  - Multiple blood samples at day 1,2 and 4 after parturition

## In Conclusion

- A predictive model can be made
- Neural networks are a promising method
- Still a long road lies ahead before widespread practical implementation

*ADSA Discover Conference on Food  
Animal Agriculture:*

## **Milking the Data – Value Driven Dairy Farming**

**May 6-9, 2024**

**Eaglewood Resort & Spa in Itasca, IL**  
Hosted by the American Dairy Science  
Association®

# ***SAVE THE DATE!***

## **Potential Conference Topics**

- Data integration across the entire dairy chain
- Adoption of technology
- Disruptive technologies
- Data governance & cybersecurity
- Mining the value of data

For complete conference information go to:

**<https://www.adsa.org/Meetings/46th-Discover-Conference>**
